Subject:	More Details for Apache2 "prefork" setup?		
Description	<p>Hello evererbody,</p> <p>I just wanted to setup a Ubuntu 7.04 vmware image with apache2 and php6 to test the framework.</p> <p>I got everything run, but The Framework doesn't worked. The spl_autoload_register didn't register any classes. :(</p> <p>I found out that the apache2 was installed as a apache2-mpm-worker (multithreaded).</p> <p>After <i>apt-get remove apache2-mpm-worker</i> and <i>apt-get install apache2-mpm-prefork</i> it worked. Yuhu! :-D</p> <p>So perhaps somebody of you can add some more details about the installation process. I think it could help other developers, too.</p> <p>Have fun on T3CON07</p> <p>I'm sorry that I can't be there ;-)</p>		

History

#1 - 2008-01-08 13:51 - Karsten Dambekalns

- Status changed from New to Closed
- Sprint set to wontfix

Well, the guide says in the part "The absolute basics" (chapter 1): *Apache Webserver, either 1.3.x or 2.x. If you use the 2.x branch, make sure to install the prefork variant.* Since systems vary too much, we cannot go into more detail here.

The wiki points out the prefork worker, too.
